

# **Applications of the Tagged Neutron Method for Fundamental and Applied Research**

Yu.N. Kopatch and TANGRA collaboration

*Joint Institute for Nuclear Research, IIO, 141980 Dubna*

The tagged neutron method (TNM) consists in irradiating the object of study with fast neutrons with an energy of about 14 MeV, which are formed in the reaction  $d+t \rightarrow \alpha+n$ . Neutron tagging is carried out by registering an alpha particle with a special position sensitive detector built into the neutron generator. The use of TNM in experiments studying nuclear reactions with fast neutrons provides a number of important advantages, in particular, a decrease in the background due to the registration of events coinciding with  $\alpha$ -particles. The study of the spectra of gamma rays produced in the reactions of inelastic neutron scattering makes it possible to carry out an elemental analysis of the irradiated object. Currently, TNM technology is widely used in various practical applications for remote non-destructive analysis of the elemental composition of a substance.

The TANGRA (TAGged Neutrons and Gamma Rays) project at JINR is aimed at investigations of the neutron-nuclear reactions using the tagged neutron method, finding new ways to use neutron methods in fundamental and applied research, improving existing and creating new approaches for processing the data collected in nuclear physics experiments.

A brief overview of recent activities in the framework of the TANGRA project will be presented with an emphasis on the measurements of the gamma-ray emission cross sections and angular distributions from  $(n,x\gamma)$  reactions with 14.1 MeV neutrons using the tagged neutron method, as well as on the development and use of the TNM for non-destructive elemental analysis of various objects.
