Aim of this work

01

Assess elemental content including heavy metals in both water and algae samples from Red sea, Arabian Gulf and Gulf of Oman.

03

Comparison between elemental content in algae samples from The Red Sea, Arabian Gulf, and the Gulf of Oman

02

Comparison between elemental content in water samples from The Red Sea , Arabian Gluf and the Gulf of Oman

04

Calculate the Enrichment factor for each element in different types of algae

2

Study Area

The Red Sea coast

Tourism Activities

Oil Mining Activities

The Red has a very unique location and is considered one of the main Marine Navigation paths connecting the Indian Ocean to the Mediterranean Sea through the Suez Canal.

Despite its important location, The Red Sea has fast-growing anthropogenic activities ranging from Oil Mining, pathing through cement and pesticide industries, and ending with tourist activities.

Shipping activities near Suez Harbor

Phosphate contamination

The Arabian Gulf region

The large extent of Oil spill

The Arabian Gulf is an extension of the Indian Ocean located in the southwest of Asia between the Islamic Republic of Iran and the Arabian Peninsula. Due to the rapid development in this region, the water resources are subjected to potential pressure and facing numerous environmental challenges. desalination plants

Sampling preparation and analysis

...

Sampling Locations:

24 algae samples and 9 samples of water were collected from 5 stations in the Red Sea, 2 stations in the Gulf of Oman, and 2 stations in the Arabian Gulf.

1: Kalba. 2: Dibba Fujairah.
3: Ras Al Khaima. 4: Dhanna Abu Dhabi.

1: Safaga. 2: Hurghada. 3: Ras Gharib.
4: Zaafrana. 5: Ain Soukhna

Sampling Collection and Preparation

Sampling Collection

All Algae samples were collected by hand at a depth of 1.5m, and all water samples were collected at a depth of 1.5 -2 meters.

Sampling preparation

All algae samples were washed from epiphytes with ambient water and transferred to the lab in an ice box. In the lab, all algae samples were washed with distilled water and dried till constant weight at 105 °C, then homogenized in a gate mortar. All water samples were treated with conc. Nitric acid and kept in a high-density polyethylene bottle at -10 °C till analysis.

Samples measurements

The elemental analysis was determined using ICP-OES Plasma Quant 9000 Elite (Analytik Jena, Germany), Frank Lab of Neutron Physics, JINR.

Samples preparation

0.5 grams of algae were placed into Teflon vessels and subjected to digestion using 5 mL of high-purity HNO_3 and 2 mL H_2O_2 .

Samples digestion

Samples were digested at 180°C in the Mars 6 microwave digestion system (CEM, USA). After cooling the digested samples were fully transferred into 50-milliliter flasks and diluted to volume with deionized water.

Quality Control

The analysis of reference material maintained the assurance of measurement quality, five certified reference materials were used to perform this analysis.

Atomization

Samples were pumped inside the sprayer and then flamed to turn into plasma.

Samples measurements

Each sample is measured separately, followed by 2% Nitric acid washing.

Detection

All detected spectrum is obtained and the concentration of each element is determined.

4

Results and Outcomes

The concentrations of Na, Mg, Al, Ca, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Sr, Cd, Ba, and Pb for all algae types were determined, while the concentrations of Cr, Co, Ni, C, Pb and Cd were below the limits of detection in water samples.

Accumulation Factors

Transfer factor

The Accumulation factor is used to describe the accumulation of a given element in the algal mass with respect to the water, according to the following equation:

$$E_f = C_{\text{algae}} / C_{\text{water}}$$

Transfere factors among different types of Algae:

Mn

Conclusion:

- 1- The concentration of Na, Mg, Al, Ca, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, Sr, Cd, Ba, and Pb in 24 samples of algae and 9 samples of water collected from the Red Sea, the Gulf of Oman, the Arabian Gulf were determined using ICP-OES.
- 2- The highest content of all elements in water samples found in samples collected from the Red Sea, except for Ba, which has its highest value in water samples collected from the Gulf of Oman.
- 3- Algae samples collected from the Gulf of Oman contained the highest values of Mg, Cr, Mn, Fe, Co, Ni, and Cu, while the content of Pb showed its highest peak in samples collected from the Zaafrana station on the Red Sea, with a value 18 times the average value of Pb among all the samples.
- 4- The lowest content of V, Cr, Mn, Fe, Ni and Pb were found in samples collected from Hurghada, The Red sea. As well as the lowest values of Co, Cu and Zn found in samples collected from Ras Gharib the Red Sea.
- 5- *Corallinalins* sp. reflected a high ability to accumulate Mg, Al, Fe and Ca and might be a potential remedial agent, While *Derbesia Lamourouxii* showed a high accumulation ability toward Na and Mn and *Garcilaria* sp is a good accumulator for Zn and might be a potential remedial agent for Zn absorption and removal.

Acknowledgment!

I would like to thank the Joint Institute for Nuclear Research, Dubna, Russia, for providing all the facilities for measuring the samples.

I would like to thank the Academy for Science and Technology for the Organization of ISINN30.

Acknowledgment

I dedicate my deepest appreciation.
